

## Objective

Find the actuator inputs (servo angle)

- I.e., find the rotation of servos (which are located at  $B_n$ ) required, such that the platform moves from the original orientation ( $PO$ ) to the final orientation  $P$ .

## Method

1. Find the distance between base joint  $B_n$  and platform joint  $P_n$  for all joint pairs based on the final desired platform orientation
2. Find the servo angle that achieves the distance between  $B_n$  and  $P_n$  while satisfying all required constraints

# Calculations

1. Find the distance between base joint  $B_n$  and platform joint  $P_n$  for all joint pairs based on the final desired platform orientation  $P$

$${}^{PO}\mathbf{p}_P = [X_P, Y_P, Z_P]^T$$

$${}^{PO}_P\mathbf{R} = \text{Rot}(\text{roll}_P, \text{pitch}_P, \text{yaw}_P)$$

To find the distance, we first describe the platform joints relative to base origin  $BO$ , since having all points in a single coordinate system makes calculation easier.

$${}^P\mathbf{p}_{Pn} \rightarrow {}^{BO}\mathbf{p}_{Pn}$$

# Key parameters

Position and rotation of base joints ( $B_n$ ) relative to the base origin (BO)

$${}^{BO}\mathbf{p}_{Bn} = [X_{Bn}, Y_{Bn}, Z_{Bn}]^T, \quad \text{for } n \in \{1 \dots 6\}$$

$${}^{BO}_{Bn}\mathbf{R} = \text{Rot}(\text{roll}_{Bn}, \text{pitch}_{Bn}, \text{yaw}_{Bn}), \text{ for } n \in \{1 \dots 6\}$$

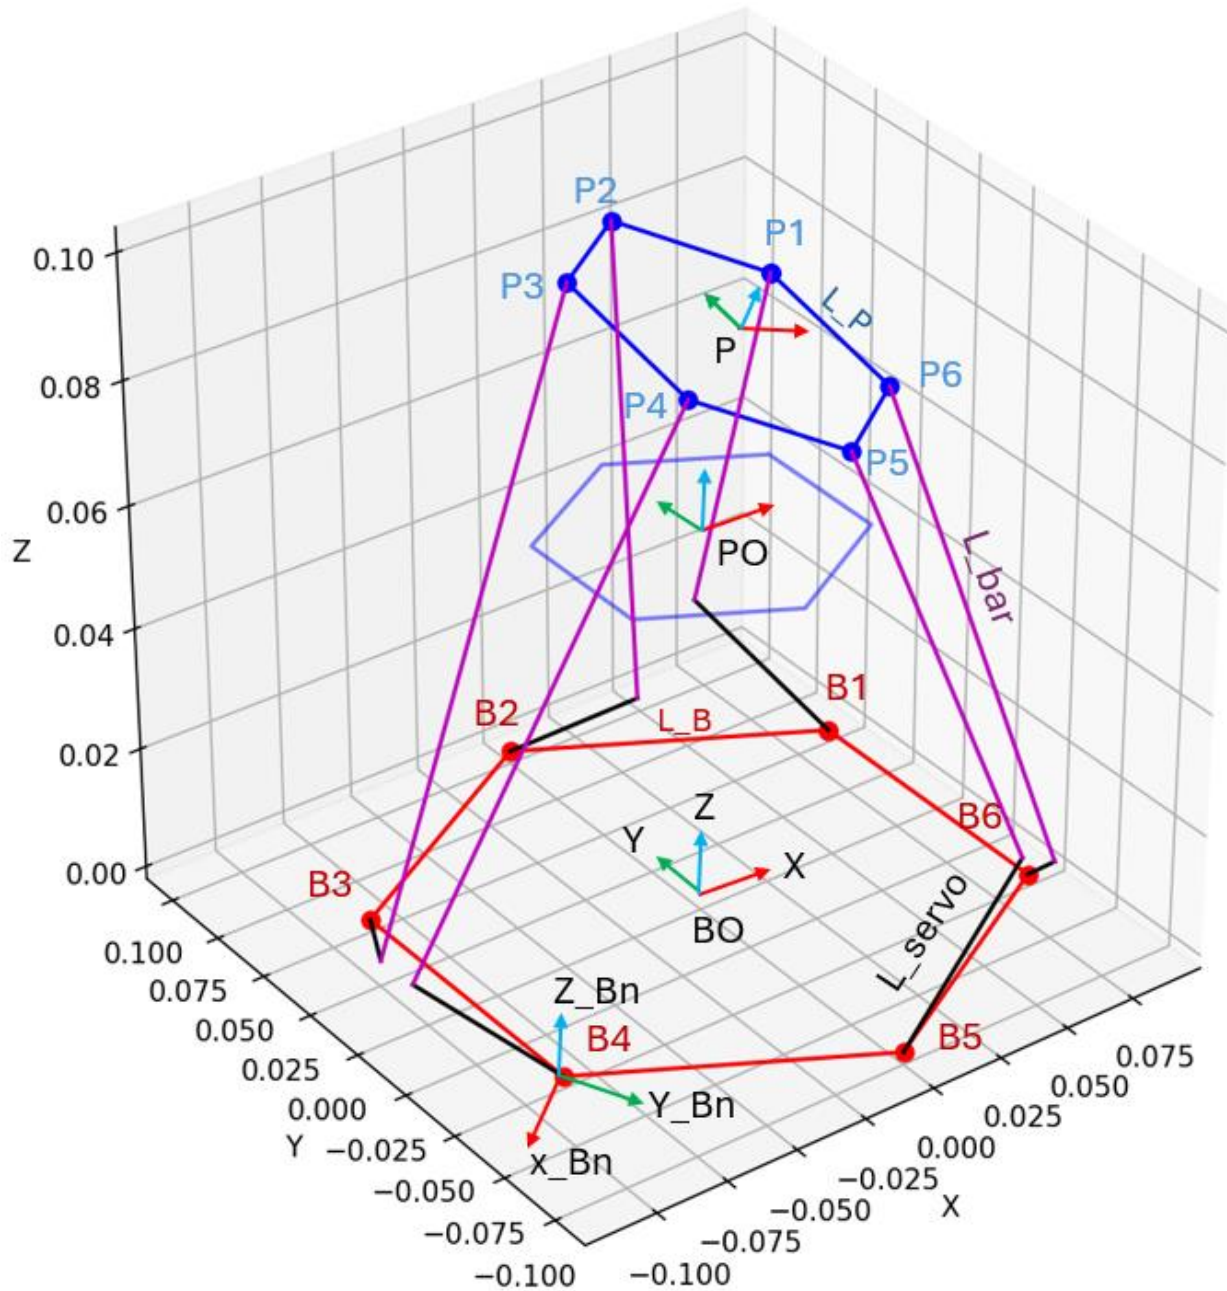

Position and rotation of platform joints ( $B_n$ ) relative to the base origin (BO)

$${}^{BO}\mathbf{p}_{PO} = [X_{PO}, Y_{PO}, Z_{PO}]^T = [0, 0, Z_{PO}]^T$$

$${}^{BO}_{PO}\mathbf{R} = \text{Rot}(\text{roll}_{PO}, \text{pitch}_{PO}, \text{yaw}_{PO})$$

Position and rotation of platform joints ( $B_n$ ) relative to the base origin (BO)

$${}^{BO}\mathbf{p}_{Pn} = [x_{Pn}, y_{Pn}, z_{Pn}]^T, \quad \text{for } n = \{1 \dots 6\}$$

# Calculations

To find the distance, we first describe the platform joints relative to base origin BO, since having all points in a single coordinate system makes calculation easier.

$${}^P\mathbf{p}_{Pn} \rightarrow {}^{BO}\mathbf{p}_{Pn}$$

This can be achieved by multiplying  ${}^P\mathbf{p}_{Pn}$  with a homogeneous transformation matrix  ${}^{BO}_P\mathbf{T}$ .

$${}^{BO}\mathbf{p}_{Pn} = {}^{BO}_P\mathbf{T} \cdot {}^P\mathbf{p}_{Pn}$$

Using the property of homogeneous transformation matrix,  ${}^{BO}_P\mathbf{T}$  can be further decomposed to,

$${}^{BO}_P\mathbf{T} = {}^{BO}_{PO}\mathbf{T} \cdot {}^{PO}_P\mathbf{T}$$

# Calculations

Using the property of homogeneous transformation matrix,  ${}^{BO}_P\mathbf{T}$  can be further decomposed to,

$${}^{BO}_P\mathbf{T} = {}^{BO}_{PO}\mathbf{T} \cdot {}^{PO}_P\mathbf{T}$$

Where,

$${}^{PO}_P\mathbf{T} = \begin{bmatrix} {}^{PO}_P\mathbf{R} & {}^{PO}\mathbf{p}_P \\ 000 & 1 \end{bmatrix}, {}^{BO}_{PO}\mathbf{T} = \begin{bmatrix} {}^{BO}_{PO}\mathbf{R} & {}^{BO}\mathbf{p}_{PO} \\ 000 & 1 \end{bmatrix}$$

and,

$${}^{PO}\mathbf{p}_P = [X_P, Y_P, Z_P]^T = \text{Func.Input}$$

$${}^{PO}_P\mathbf{R} = \text{Rot}(\text{roll}_P, \text{pitch}_P, \text{yaw}_P) = \text{Func.Input}$$

$${}^{BO}\mathbf{p}_{PO} = [X_{PO}, Y_{PO}, Z_{PO}]^T = [0, 0, Z_{PO}]^T$$

$${}^{BO}_{PO}\mathbf{R} = \text{Rot}(\text{roll}_{PO}, \text{pitch}_{PO}, \text{yaw}_{PO}) = \text{Rot}(0,0,0)$$

## Calculations

Once  ${}^{BO}_P\mathbf{T}$  is found, we can find platform position  $\mathbf{p}_{Pn}$  described in the coordinate system of the base origin BO.

$${}^{BO}\mathbf{p}_{Pn} = {}^{BO}_P\mathbf{T} \cdot {}^P\mathbf{p}_{Pn}, \quad \text{for } n \in \{1 \dots 6\}$$

The position of base joints Bn relative to the base origin BO is predefined (i.e., dependent on design itself).

$${}^{BO}\mathbf{p}_{Bn} = [X_{Bn}, Y_{Bn}, Z_{Bn}]^T, \quad \text{for } n \in \{1 \dots 6\}$$

# Calculations

2. Find the servo angle that achieves the distance between  $B_n$  and  $P_n$  while satisfying all required constraints

For linear actuators, the derived lengths between the platform joints  $P_n$  and the base joints  $B_n$  can be used.

$$L_n = |{}^{BO}\mathbf{p}_{P_n} - {}^{BO}\mathbf{p}_{B_n}| = \text{norm}({}^{BO}\mathbf{p}_{P_n} - {}^{BO}\mathbf{p}_{B_n})$$

However, for a Stewart Platform with servo motors, the offset due to the servo rotation must be considered.

# Calculations

To find the required servo rotations, multiple physical constraints must be satisfied.

First, the length between the platform joint  $P_n$  and base joints  $B_n$  must satisfy the following as derived earlier.

$$L_n = |{}^{BO}\mathbf{p}_{P_n} - {}^{BO}\mathbf{p}_{B_n}| = |{}^{B_n}\mathbf{p}_{P_n} - {}^{B_n}\mathbf{p}_{B_n}|$$

Second, the servo arm can only be on the YZ plane of the base joints' coordinate systems. I.e., the servo rotates around the x-axis of base joint's x-axis.

$$y_{B_n}^2 + z_{B_n}^2 = L_{servo}^2$$

## Calculations

Third, since the length from the end-effector (tip of the servo arm) and the platform joint  $P_n$  is connected by a bar, this length must be constant.

$$(x_{P_n} - x_{B_n})^2 + (y_{P_n} - y_{B_n})^2 + (z_{P_n} - z_{B_n})^2 = L_{\text{bar}}^2$$

Where all coordinates are described relative to base joint  $B_n$ .

Finally, since the joint between the servo arm and bar can only be on the YZ plane of  $B_n$ ,

$$x_{B_n} = 0$$

## Calculations

All constraints:

$$L_n = |{}^{BO}\mathbf{p}_{Pn} - {}^{BO}\mathbf{p}_{Bn}| = |{}^{Bn}\mathbf{p}_{Pn} - {}^{Bn}\mathbf{p}_{Bn}|$$

$$y_{Bn}^2 + z_{Bn}^2 = L_{servo}^2$$

$$(x_{Pn} - x_{Bn})^2 + (y_{Pn} - y_{Bn})^2 + (z_{Pn} - z_{Bn})^2 = L_{bar}^2$$

$$x_{Bn} = 0$$

# Calculations

By substitution, following equations can be found.

$$(4y_{Pn}^2 + 4z_{Pn}^2) \cdot y_{Bn}^2 + 4y_{Pn}D \cdot y_{Bn} + D^2 - 4z_{Pn}^2L_{servo}^2 = 0$$

$$z_{Bn} = \sqrt{L_{servo}^2 - y_{Bn}^2}$$

Where,

$$D = L_{bar}^2 - L_{servo}^2 - x_{Pn}^2 - y_{Pn}^2 - z_{Pn}^2$$

Solving the quadratic equation, it is possible to find  $y_{Bn}$ , and by substituting,  $z_{Bn}$  can be found.

# Calculations

Once  $y_{Bn}$  and  $z_{Bn}$  are found, check that the solution satisfy the final constraint,

$$L_n = |{}^{BO}\mathbf{p}_{Pn} - {}^{BO}\mathbf{p}_{Bn}| = |{}^{Bn}\mathbf{p}_{Pn} - {}^{Bn}\mathbf{p}_{Bn}|$$

Where,

$${}^{Bn}\mathbf{p}_{Pn} = [x_{Pn}, y_{Pn}, z_{Pn}]^T$$

$${}^{Bn}\mathbf{p}_{Bn} = [x_{Bn}, y_{Bn}, z_{Bn}]^T$$

Finally, the servo angles can be found by,

$$\theta = \arctan\left(\frac{z_{Bn}}{y_{Bn}}\right)$$
